About the Study

The New Jersey Childhood Obesity Study, funded by the Robert Wood Johnson Foundation, aims to provide vital information for planning, implementing and evaluating interventions aimed at preventing childhood obesity in five New Jersey municipalities: Camden, Newark, New Brunswick, Trenton, and Vineland. These five communities are being supported by RWJF's New Jersey Partnership for Healthy Kids program to plan and implement policy and environmental change strategies to prevent childhood obesity.

Effective interventions for addressing childhood obesity require community specific information on who is most at risk and on contributing factors that can be addressed through tailored interventions that meet the needs of the community.

Using a comprehensive research study, the Center for State Health Policy at Rutgers University is working collaboratively with the State Program Office for New Jersey Partnership for Healthy Kids and the five communities to address these information needs. The main components of the study include:

- A household survey of 1700 families with 3 -18 year old children
- De-identified heights and weights data from public school districts
- Assessment of the food and physical activity environments using objective data

Data books and maps based on the results of the study are being shared with the community coalitions in the five communities to help them plan their interventions.

In This Chartbook...

The maps in this chartbook describe the food environment in Newark in terms of access to supermarkets, smaller grocery stores, convenience stores, and limited service restaurants. Research shows that when residents have access to healthy food outlets, they tend to eat healthy.

- Food environment maps were created using geo-coded commercially available data of food outlets (InfoUSA, 2008 and Trade Dimensions, 2008) in Newark and in a 1 mile buffer area around Newark.
- Using the commercial data and additional investigation, food outlets were classified into different categories based on their likelihood of carrying healthy choices: supermarkets carry most healthy choices; smaller grocery stores carry fewer healthy choices; convenience stores and limited service restaurants are likely to carry mostly unhealthy choices.
- Access to different types of food outlets was computed at the census block group level based on concentration of stores / restaurants per unit area and is reported as food outlet densities.
- Food outlet density maps are compared with Census 2000 data to visualize accessibility of healthy food s in neighborhoods with different characteristics.

The map shows convenience store densities at the block group level. Convenience stores (red dots) in Newark and within a 1 mile buffer of city boundaries are mapped. Block groups with darker colors have higher access to convenience stores.

Next Steps

- As part of the New Jersey Childhood Obesity Study we have also conducted a household phone survey.
- The results from the survey related to children's BMI, health behaviors, parental perceptions of environments will be linked to the food environment data presented in the preceding maps.
- Using the survey and food environment data, we will be able to address questions such as:
 - ✓ What aspects of the food environment are associated with childhood obesity?
 - ✓ How are environmental characteristics associated with eating behaviors?
 - ✓ How important are perceptions of the environment as compared to actual neighborhood characteristics in contributing to childhood obesity? To eating behaviors?
 - ✓ How do these relationships differ among various socio-demographic groups (e.g., gender, race-ethnicity, social class)?
